On our cover: a male Puerto Rican Sharp-shinned Hawk glances up at his mate as the pair search the hurricane-ravaged forest for a nesting site in early 2018. They built a nest and were preparing for eggs within a few days when she was taken by a predator. Her loss was particularly tragic, as she was one of the last 19 of the species known to survive at the time. Read more on page 31.

The new year is full of promise for the male; in 2019 our biologists found him courting a new female, who appeared to have chosen him over two other potential mates. Thanks to Russell Thorstrom, the project manager, for contributing this photo.

Look for these icons to see how each project in the following pages fits into Vision 2050, our strategic plan to change the future.

Dear Friends

It all started with a phone call.

Founding Director, Jim Weaver, was on the other end of the line and the topic at hand—Puerto Rico. It wasn't long after Hurricane Maria had devastated the island and he was concerned about the fate of the Critically Endangered Puerto Rican Sharp-shinned Hawks. Over the past few years, Peregrine Fund scientist Russell Thorstrom closely monitored the Sharp-shinned population across the island so we knew there were only about 75 individual hawks remaining. The big question on Jim's mind—how did the hurricane impact their numbers?

Russell boarded a plane to see for himself. Picking their way through downed trees and previous nesting sites that had been reduced to toothpicks, Russell and the team located only 19 birds. It was time for alarm and, more importantly, action.

If we have one specialty at The Peregrine Fund, it is recovering critically endangered birds. Leveraging decades of expertise, we went to work drafting a recovery plan. Recognizing that the conservation of a species requires significant resources, we began fundraising to save this species.

This time, you were the one who answered the call.

You motivate us and drive our mission, keeping us steadfast and focused.

Your financial support brought boots to the ground, fueling a team of biologists and volunteers to monitor nesting behavior of the few remaining hawks, working to boost their breeding success by incubating eggs and hand-rearing nestlings, and providing supplementary food in the wild. Peregrine Fund board member, Victor Gonzalez, even allowed us to transform his home in Puerto Rico into a fully functional hawk nursery.

Because of people just like you, we added six hand-reared and two wild-reared birds, resulting in a 42% population increase.

In all my years protecting raptors around the world, I've come to understand that **the power of The Peregrine Fund is its people**. It's the scientists in the field saving species on a shoestring, the volunteers who come with ready hands and passionate hearts, our leadership team and staff who steer the ship. But, you are the ultimate catalyst for change. You motivate us and drive our mission, keeping us steadfast and focused. Our gratitude is beyond words.

In conservation,

A handwritten signature in blue ink that reads "Rick". The signature is stylized and includes a long horizontal stroke underneath.

*Richard T. Watson, Ph.D.
President and CEO*

the people of THE PEREGRINE FUND

"Birds of prey have a very special place in my heart. The first bird I ever helped was an Augur Buzzard, which was injured by a boy in my high school. We stayed with the bird in our school museum for some days and fed it termites until it had recovered strength. That experience left me knowing that birds need our help just like our friends and family."
Washington Wachira,
Peregrine Fund supported Masters Student and East Africa Project Biologist

"The work we do helps to ensure a healthy world, and I'm proud of my role working with our members. We have so many long-term members that have continued to support our work over the years. They are our partners in conservation!"
Linda Behrman,
Director of Membership and team member for 31 years

"What we do is important because we find solutions to emerging problems, and help make a difference in worldwide conservation. I'm most proud of our team of people who are willing to work offsite, off hours, during weekends, over the phone, to take care of our birds and facilities without the expectation of reward. We do it because we care and we believe in the importance of what we do."
Carolina Granthon,
Propagation Specialist and team member for six months

"If I were to describe the people of The Peregrine Fund, the words I would use are, 'committed to a common vision.' Their vision is to achieve conservation on a global scale that is carried out with scientific integrity. That dedication and enthusiasm inspires everyone involved with The Peregrine Fund, and it feeds off itself, generating its own excitement."
Carter Montgomery,
Peregrine Fund Board Chairman and Director for more than 40 years

the people of THE PEREGRINE FUND

"I love birds of prey: their prowess, their dusty smell, their feathered wings, their fierce glowing eyes, their needle-sharp talons and strong leather-skin feet; to see one fly is a breathtaking experience that all people should have the chance to experience. I am so grateful to be a part of this organization that exists to make the world a better place for all creatures and lets me spread my own wings in contribution."

**Christine Hayes,
Peregrine Fund
supported Masters
Student and Ridgway's
Hawk Project Biologist**

"Raptors are positioned at the apex of the food chain, and as such they serve as indicators of the health of the entire ecosystem. Having a healthy population of raptors is a sign of an intact ecosystem. For me, conserving raptors means caring for our own health, so it is important that we think and act for raptors' welfare. Because of the training I received from The Peregrine Fund, I am more confident to explore new ideas for the conservation of raptors in my country."

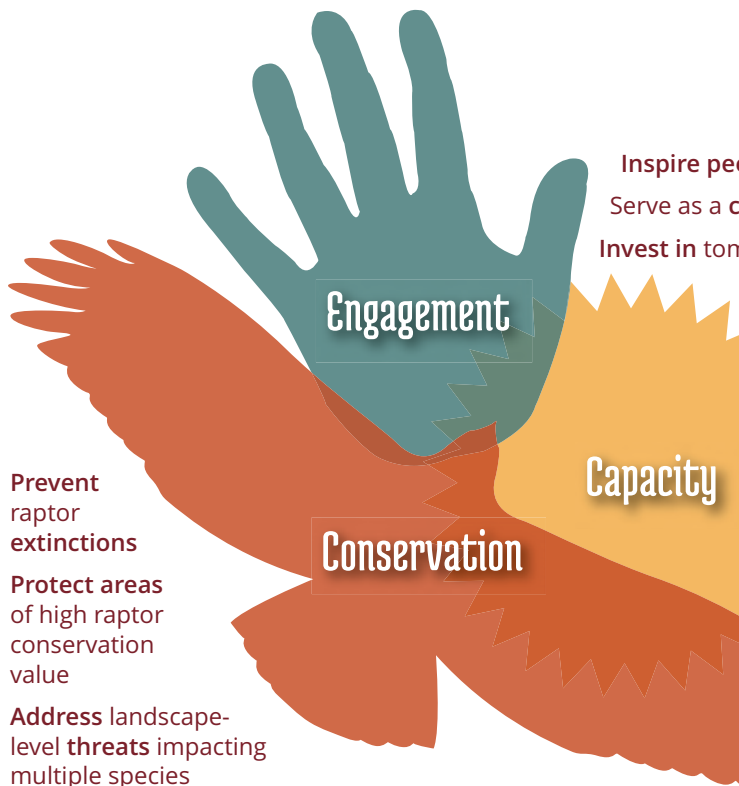

**Dr. Tulsi Subedi,
Peregrine Fund
supported and recently
graduated Ph.D. Student
and Asia Project Biologist**

"We make a positive impact on the well being of our planet by saving species that are on the brink, by enriching the lives of so many communities around the world, by inspiring the hearts of millions, young and old, to care for the wild, and by providing unparalleled knowledge to future conservation leaders to ensure human-wildlife coexistence. This work is exciting because we have a unique group of people whose combination of talent, skills, personalities, creativity, beliefs, and passion make us who we are! We just get the work done!"

**Dr. Munir Virani, Vice
President and Global
Director of Conservation
Strategy and team
member for 27 years**

"Great conservation organizations are those that stay focused, know what success looks like, and deliver results. The Peregrine Fund embodies those qualities and has established a clear track record as the unquestioned field-leader in bringing endangered raptors back from the brink and enabling them to recover. They have a critical role to play in protecting some of the world's most spectacular birds as they set their sights on a more ambitious global role and reach."

**Acacia Conservation
Fund**

Inspire people to value raptors and take action

Serve as a catalyst for change

Invest in tomorrow's conservation leaders

Assemble infrastructure, facilities, and people

Raise sufficient funds to execute actions, achieving measurable, timebound goals on an iterative five-year cycle

Prevent raptor extinctions

Protect areas of high raptor conservation value

Address landscape-level threats impacting multiple species

5-year action plans

CONSERVATION OUTCOMES

- Global Raptor Impact Network
- Recovering the Northern Aplomado Falcon
- Golden Eagle Conservation on U.S. Dept of Defense Lands
- Propagation at World Center for Birds of Prey

Vision 2050 to CHANGE THE FUTURE

is ambitious, specific, unifying, inspirational, measurable, and—most importantly—empowering to the people and communities who bring it to life.

What does success look like?

Raptor populations and their environments thrive

Human communities are enriched by our work and raptors are valued by all

We are the world leader for conserving birds of prey

THE
PEREGRINE
FUND

Our Core Values

We cherish birds of prey.

Sound scientific knowledge is our foundation.

We embrace diversity.

Integrity is precious and paramount.

Saving birds of prey is our life's work.

Global Raptor Impact Network (GRIN)

Interface of the new GRIN smartphone app.

How can scientists prioritize conservation actions for all raptor species on Earth? What tells us if a species is stable or endangered? The answers are complex, and even the world's most complete, up-to-date inventory of species is compiled from reports published years or even decades ago.

Eliminating that time lag could revolutionize conservation, setting a new pace for recognizing species declines...

Our Impact

Available soon for Android and iOS devices, our new app will be a free tool for professional and citizen scientists to collect raptor data on a mobile device. Sightings, nest productivity, mortality, resightings, museum specimens, and more can be collected. The app will enable researchers to conduct studies directly in the field, eliminating tedious data entry at home or in the office.

We launched the world's first online database of diurnal raptors in 2005, forming a community of professional raptor biologists and students around the globe who contributed published work. This database, the **Global Raptor Information Network**, is the foundation of the new **Global Raptor Impact Network**, a more robust platform for contributing, analyzing, and sharing current data.

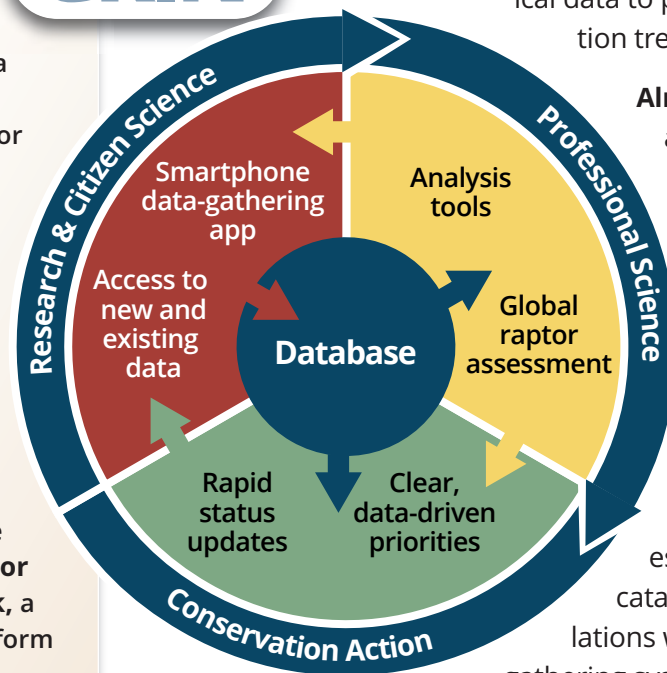

Critically endangered species don't have time to wait, especially those faced with rapidly growing threats like poison, electrocution, land development, and climate change. Accelerated threats must be met with accelerated tools to find and respond to populations in crisis.

Our new **Global Raptor Impact Network (GRIN)** will unify raptor data into a single, nimble network that is large enough to **identify threats and population trends in real time**.

We helped launch the African Raptor DataBank as a pilot program in collaboration with Habitat Info and other partners to collect data over a five-year period. More than 180,000 data points were collected via a smartphone app by dozens of scientific and conservation groups across the African continent. With this new information, a striking amount of lost habitat, hotspots of poisoning and electrocution, and sites with the best remaining habitat were mapped. **The result: six African vulture species were uplisted**, some to Critically Endangered status, on the Red List published by the International Union for the Conservation of Nature. Subsequent funding and attention to the plight of Africa's vultures increased significantly.

Based on the success of the African Raptor DataBank, we are now scaling it up for global use as GRIN. A beta version of the smartphone app was released to researchers at the 2017 Raptor Research Foundation conference, and developers launched the new website **globalraptors.org** in 2018. Besides serving as a collection point for new, real-time data, GRIN can house and safeguard historical data to provide a baseline for tracking population trends over long time periods.

Already, the data collected through GRIN are more comprehensive than any data set currently existing for raptors, and includes first-time global data sets on lifespan, productivity, diet, and habitat. We can accurately map the range, demography, and behaviors of raptor species and identify trends quickly.

The ability to recognize trends across a broad landscape or a set of species is especially valuable. For example, the catastrophic decline in Asian vulture populations was difficult to quantify with the data-gathering systems of the 1990s. If a similar

catastrophe occurs now, GRIN will enable us to quickly assess the trend and sound the alarm.

01/2019

North American Non-Lead Partnership

Hunters and anglers often have the deepest and most respected voices within the chorus of support for wildlife in North America. Showing pride in their heritage—protecting the delicate balance of predators, prey, and scavengers—sportsmen and women contribute more than a billion dollars each year toward conservation.

When wildlife is under threat, hunters are among the first to notice and act. That's why we're alerting them to a safer choice of ammunition...

THE PEREGRINE FUND

Our Impact

To recover a wild California Condor population in the Grand Canyon region, we have collaborated with state wildlife managers since 2003 to incentivize lead reduction actions for hunters in northern Arizona and southern Utah. For nearly a decade more than 80% of those deer hunters have taken voluntary actions to help prevent exposure.

When we held our groundbreaking 2008 symposium “Ingestion of Lead from Spent Ammunition—Implications for Wildlife and Humans,” existing and new partners eagerly participated to see the latest research and help craft solutions.

Late summer of 2018 we co-founded the North American Non-Lead Partnership, a collaborative currently consisting of three state wildlife agencies, three conservation organizations, and seven sports/hunting groups aligned by a mission to preserve our wildlife conservation and hunting heritage through voluntary incentive-based outreach and education aimed at increasing the use of non-lead alternatives.

Hunters are heroes for scavenging animals, particularly in winter when a gut pile or carcass can prevent starvation. Unfortunately, the smallest trace of lead ammunition in that valuable food source causes unintended side effects. Unlike monolithic solids such as all-copper bullets, lead bullets scatter into microscopic fragments. Scientific evidence from numerous sources shows that lead-tainted meat is by far the primary source of lead poisoning in wildlife. An animal that eats lead is sickened and can die slowly from failure of the central nervous system—certainly not the aim of an informed, ethical shooter.

Lead was routinely included in paint, fuel, and even food prior to medical discoveries in the last century. And as residents of Flint, Michigan, can attest, ending exposure to this preventable threat is a major undertaking with high stakes—protecting the health of our most vulnerable. Those vulnerable residents include raptors like eagles and vultures whenever remains of shot animals are left in the wild. **Even the mighty California Condor, with its nine-foot wingspan, can die after eating lead from ammunition residues.**

Copper ammunition (left) does not fragment like lead-based ammunition.

The North American Non-Lead Partnership is committed to working with hunters to end lead poisoning of wildlife by increasing the use of non-lead ammunition. The hunting community took steps in 1991 to manage the use of lead shot for waterfowl, with positive results for Bald Eagles and game animals alike. To expand on that protective effect, we’re asking shooters for a simple, voluntary fix: switch to non-lead ammunition for instances where meat or a gutpile might be left for wild animals to scavenge.

In addition to advocating for this voluntary switch, the partnership supports ongoing research about lead exposure pathways. Sound science is one of the pillars of American hunters’ conservation ethic, and the partnership’s roots are in long-established, well-respected scientific organizations.

The partnership does not seek to ban lead ammunition, firearms, or hunting. Its singular focus is safeguarding wildlife—an achievable goal with the help of hunters, America’s first conservationists.

American Kestrel

Kevin Smith

Rob Palmer

American Kestrels are North America's most plentiful falcon, guarding cityscape ledges or hovering over rural roadsides to hunt rodents and insects. This small falcon is familiar even to casual observers, but a look at population levels reveals a perplexing mystery: continent-wide, kestrels have declined by nearly half since the 1960s.

Researchers have yet to find the definitive threat—or threats—that are making this “common” species uncommon. As the global specialist for birds of prey, we have united researchers to develop the “big picture” before it’s too late...

Our Impact

Professional and citizen scientists have contributed 25,000 observations and 4,500 boxes in total, getting us closer to understanding the mystery of the slow, steady, and long-term decline of the American Kestrel.

Our partners have contributed more than 700 blood or feather samples from across the continent for genetic analysis, helping scientists better understand kestrel populations across North America.

By tuning into the KestrelCam and telling us what they saw, our citizen scientist partners contributed more than 27,000 observations of a single kestrel nest box from 2012–2017. We found that 88% of observations are accurate. We published the findings and are encouraging the greater conservation community to consider wildlife webcams as an untapped opportunity to conduct citizen science.

We are initiating winter survival studies to better understand what is happening with American Kestrels outside of the breeding season.

The American Kestrel ranges from the Yukon to Tierra del Fuego, so compiling a “snapshot” of kestrel life requires a veritable army of observers. Fortunately, kestrels are cavity-nesters and readily inhabit nest boxes during the breeding season, making observation relatively simple so that virtually anyone can contribute data to our continent-wide study. “Citizen scientists” are the eyes, ears, and hearts of the American Kestrel Partnership, contributing countless hours and enthusiasm and creating an international community throughout the Americas to unite people based on love for their backyard falcon.

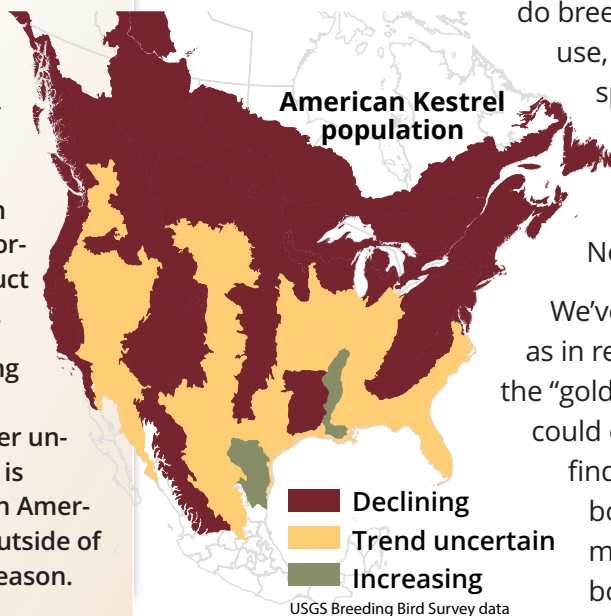

Although many local nest box programs exist, the American Kestrel Partnership is the only coordinator of an international network of professional and citizen scientists, managing a single database to look for far-reaching trends that could explain population declines.

Jim Shane

Now with five years of data, we have narrowed our inquiry to go beyond simple “head counts” and delve into questions about the kestrel’s life cycle. Are adults returning after winter to breed? Are they dying at high rates during breeding, migration, or over-wintering? Are they breeding less often, or failing when they do breed? And, critically, how are they affected by land use, contaminants, climate, predators, and other species? To find answers, our colleagues at Boise State University and UCLA are conducting genetic analyses using feather samples gathered by our partners throughout North and South America.

We’ve also discovered that in nest box studies, just as in real estate, location is key. Nest boxes are not the “golden ticket” to halting population declines, and could even harm wildlife if placed incorrectly. These findings reinforce our focus on responsible nest box placement and standardized, consistent monitoring to ensure that American Kestrel boxes are placed in safe locations.

1/2019

Aplomado Falcon

After an absence of at least forty years, a stable Aplomado Falcon population thrives along the Gulf Coast thanks to our breeding and release program, in partnership with landowners and collaborators. So why is this falcon still on the U.S. Endangered Species List?

The wild population has yet to exceed the recommended threshold of 60 pairs. We found the root problem, then adapted our strategy...

Our Impact

Hurricane Harvey in August of 2017 severely impacted the Texas population, which lost about 30%. We found 26 pairs this year—13 fewer than in 2017—and confirmed 19 pairs nested. Productivity improved (1.7 young per pair); 43 young were produced.

We replaced 10 nest boxes and repaired 43. Ten more were placed at new locations.

Thanks to Lee Banning Offroad Racing Team we built 15 aluminum nest boxes. Fabrication costs more, but they weather better than wood boxes, reducing long-term labor and repairs. We'll continue phasing them in.

We acquired a Scientific Research Permit from the National Park Service (NPS), so Padre Island National Seashore's excellent coastal habitat is now part of the recovery. Two nest structures were placed where falcons have recently been observed.

Prairie restoration continues on USFWS Refuge and NPS lands. With chemical, mechanical, and prescribed fire methods, we are improving grasslands for many bird species.

01/2019

Unlike Peregrine Falcons that range across a variety of habitats, Aplomado Falcons depend on wide-open grasslands with mature yucca plants for nesting, ample migrating birds as prey, and a balance of other predators. Intact grasslands had become so scarce that in 2013 **we stopped breeding and releasing Aplomado Falcons and focused our efforts on finding and nurturing habitat.**

Overgrown brush is an enemy of healthy grasslands because it crowds out yucca, the falcons' preferred nesting plants, and harbors predators like Great Horned Owls. Brush removal is difficult and expensive, but the benefits for falcons and other species are significant. We now advise agencies on grassland restoration and are seeking private landowners who can commit to the same actions. Our priority is restoring areas with recently-abandoned Aplomado territories, or occupied territories where brush is beginning to encroach.

To offset a lack of yucca plants, we erected dozens of barred nesting platforms. Pairs using them raise as many young as pairs in yucca nests, and twice as many as pairs nesting on brush or the ground!

Dave Allen, allenwildlife.com

Our advanced computer analysis, the "Aplomodel," confirms that **our approach is working: reproduction along the Texas Gulf coast is ample to sustain a growing population in suitable habitat.** Despite damage from Hurricane Harvey, the Aplomado Falcon is still on its way to reaching the de-listing goal of 60 pairs.

How will we continue to grow the population? **Expanding habitat is key.** Although the Aplomado is a medium-sized falcon, it requires a relatively large area to nest and raise young. Roughly a third of the population and its habitat still lacks formal protection, and rapid development in the Lower Rio Grande Valley could pose a threat. Fortunately, we've spent decades stitching together a patchwork of private lands, public parks, and wildlife refuges. So far we have included 2.25 million acres within the falcon's historical range, with a fraction currently suitable for Aplomado Falcons.

Next year we will gather partners to share the latest knowledge and refine this species' recovery plan, which was first drafted in 1990.

California Condor

Alan Clamplit

Long before humans arrived in North America, these finely tuned scavengers relied in part on hunters—sabertooth cats and other large predators—for carrion. Condors’ clean-up role hasn’t changed, but new hunters to the scene can unintentionally leave behind a deadly contaminant: lead from spent ammunition.

Despite our efforts to recover this critically endangered species through captive breeding, release, and monitoring, preventable lead poisoning stands in the way. But like these giants of the sky, we’re learning to rely on hunters...

Our Impact

We began breeding California Condors in 1993 at our facility in Boise, Idaho. They go to release sites in Arizona, California, and Baja Mexico. We initiated the southwestern release program in 1996 at what is now the Vermilion Cliffs National Monument, Arizona.

We have re-established a free-flying population now numbering 90 condors ranging from the Grand Canyon into Utah. We annually health-check every condor we can trap. Last season, 87% of those trapped tested positive for lead exposure, and we treated 33 condors for extreme lead exposure.

Seventeen pairs in the Arizona-Utah flock showed breeding behavior this year, eight laid eggs, three hatched chicks, and three survived to fledging age.

The public can see the first free flights of captive-bred juveniles from our Vermilion Cliffs release site each September on National Public Lands Day. Year-round, our Condor Cliffs exhibit in Boise, Idaho, offers a closer look at these impressive birds.

1/2019

The California Condor is a hardy species that survived mass extinctions of the last Ice Age, yet **the entire population was reduced to just 22 individuals** by the 1980s. Scientists suspected that lead poisoning played a role in the species' decline, and recent research by The Peregrine Fund confirmed that over half of all condor deaths are due to this one preventable cause. The 'aha' moment occurred when we x-rayed deer harvested with common lead-based bullets. A constellation of tiny fragments, too numerous to count, appear in the tissue surrounding the bullet's path. Not only do California Condors ingest this lead, it's evident that many other species, even humans, may be exposed to lead-tainted meat. Like the canary in the coal mine, the California Condor has alerted us to an unforeseen and preventable hazard.

Chris Parish

By switching to non-lead ammunition, **hunters can eliminate the potential for lead exposure to any animal.** Thanks to our work with Arizona and Utah wildlife agencies over the last decade, more than 80% of deer hunters on Arizona's Kaibab Plateau now take voluntary actions to prevent exposure. Their conservation ethic will inspire others to make the switch to copper, but we need to spread the message to a wider audience.

To accomplish this, we have united to form a **North American Non-Lead Partnership**, whose sole purpose is to reach hunters, shooters, and other sporting and conservation groups with information about preventing lead poisoning.

The world population of California Condors continues to grow slowly, with **more than 400 now in existence.** More than half live in the wilderness, ready to fill their niche as skilled scavengers if only we can make their world a little safer.

California Condor Conservation Breeding

Hana Weaver

Marti Jenkins

By the time most California Condors mature to reproductive age at about six years, they have encountered a wealth of dangers in the wild. Surviving predators, accidents, and toxins is no guarantee of breeding success though—condors’ first nesting attempts often fail before the chick is old enough to leave its nest cave, and chicks that do fledge depend on their parents for a year or more. Usually, a condor pair in the wild raises a single offspring every other year.

Nature has set the stage for condor populations to grow very slowly, so our breeding program is essential...

Our Impact

We manage the world's largest captive California Condor population, totaling 65 condors—15 pairs, four unpaired adults, 15 juveniles, 14 chicks, and two on view at our visitor center. In 25 years, we've raised 271 California Condors. Some condors that are considered too genetically valuable for release continue as breeders or join our education staff at the World Center for Birds of Prey.

With advice from geneticists, we adjust the pairings when appropriate and transfer or exchange viable eggs with other facilities to maintain as much genetic diversity as possible in the total California Condor population.

We double the production of chicks from genetically desirable pairs by removing the first egg produced early in incubation and giving it to one of our unpaired adults to hatch. This allows the pair to produce a second egg and ensures that both resulting chicks have the benefit of being raised by condors.

California Condors would almost certainly be extinct if not for breeding programs, which started in the 1980s with the last 22 condors removed from the wild. The Peregrine Fund was invited by the U.S. Fish and Wildlife Service to breed condors at its World Center for Birds of Prey in Boise, Idaho, beginning in 1993. We work closely with partners coordinated by the U.S. Fish and Wildlife Service, including the three zoos that breed condors (Los Angeles, San Diego, and Oregon). Together we set annual goals for the number of condors to be produced, and designate where the previous year's chicks should be released.

By controlling risks like predators, accidents, and food contamination, we enable our captive breeders to consistently achieve success rates above 90 percent. More than half of all California Condors raised in breeding programs, 16–20 young each year, come from our facility in Boise and are divided among several release sites, including the one we manage near the Grand Canyon.

Our propagation specialists are experienced field biologists with a keen awareness of condor behavior and social structure. They create conditions that not only keep condor parents secure and content, but also prepare the young hatchlings to become wild survivors.

Because condors are highly intelligent and curious, they can

rapidly learn to associate humans with food rewards. This can spell disaster for a condor, especially one destined to fly free near a high-tourist area like the Grand Canyon. To keep our young condors from becoming familiar with humans, we design their enclosures so they rarely see or hear people. We even employ a small herd of goats to clear nearby brush rather than using mowers!

Thanks to the success of condor breeding programs, four of the original 22 are so well-represented in the wild population's genetics that they are no longer needed for breeding. **Those hardy, long-lived birds returned to the wild homes they inhabited forty years ago to live their remaining years with hundreds of free-flying descendants—no longer the “last” of their kind.**

Conservation Breeding

Jeannie Konkel

Paul Spurling

A single, fertile egg can hold the fate of an entire species inside its fragile shell— a fact woefully apparent to our founders as they struggled almost 50 years ago to coax a viable egg from the Peregrine Falcons entrusted to them. Even more rare and precious were the tiny eggs laid by the last four Mauritius Kestrels in our care a few years later.

Those early experiences led to breakthroughs in biology and species recovery, and they also laid the foundation for **The Peregrine Fund: raptor breeding experts and, more importantly, dedicated people who find a way no matter how daunting...**

THE PEREGRINE FUND

Our Impact

Our current breeding population at the **World Center for Birds of Prey** consists of 16 Taita Falcons, two female Orange Breasted Falcons and 65 California Condors.

Taita Falcons (right) show signs of decline in their native East Africa. We established a breeding protocol in case restoration is necessary.

In 2018, we began assisted propagation of the **Puerto Rican Sharp-shinned Hawk** after Hurricane Maria. First-clutch eggs were removed from wild nests, allowing pairs to produce a second clutch. We hatched the removed eggs at a facility in Puerto Rico, raising chicks in sibling groups until old enough for release. This effort essentially tripled production for 2018.

We assist worldwide in establishing breeding programs. In Hawaii, for example, we hatched endangered songbirds in captivity for the first time, then transferred the facility to local partners. We support the Philippine Eagle Foundation with breeding and release experience we've gained working with large forest eagles like the Harpy Eagle.

01/2019

Since hatching our first Peregrine Falcon in 1973, we have served as the global expert in captive propagation of endangered birds of prey. **Those last four Mauritius Kestrels were the forebears of a now-thriving population, and the lessons we learned have been handed down as well.** Altogether our staff has reared more than 4,000 Peregrine Falcons, 2,000 Northern Aplomado Falcons, and 270 California Condors—plus 19 other species from Harpy Eagles to Puerto Rican Sharp-shinned Hawks. Today we manage the world's largest captive population of California Condors, the most endangered bird in North America.

Kate Davis

Our methods are widely published, and have in fact enabled others to breed birds of prey around the world, both for falconry and for scientific and conservation pursuits. No other organization, however, has the facilities and experience to breed a variety of raptors at a similar scale—a scale that could be called upon if a raptor species suffers catastrophic decline. As threats to birds of prey increase across the globe, we are constantly refining our skills in case extreme measures are needed to prevent extinction.

Conservation breeding is not always the best solution, however; it requires careful laboratory controls, round-the-clock staff, transportation of young birds to wild release sites, and field attendants to support young birds as they learn to hunt and defend themselves—all at a heavy financial cost that may not show positive results for years.

For some species, early intervention can curtail the need for intensive conservation breeding. In the Dominican Republic we perfected a new technique of relocating young Ridgway's Hawks from their parents' nests to a safer territory before they learn to fly. This "assisted dispersal" approach has resulted in an entirely new, self-sustaining population of hawks, buying us time to address the threats that had reduced their numbers, like human persecution and habitat loss.

Gyr Falcon

David Anderson

Roy Toft

The Gyr Falcon is a raptor of extremes: not only is it the largest falcon on Earth, it's also one of the few animals adapted to harsh Arctic winters. Unfortunately, it is also considered the North American bird species most vulnerable to climate change.

Like polar bears and harp seals, Gyr Falcons can only survive in cold climates. Against a backdrop of shifting prey availability, fluctuating weather, and competition from other species moving northward, the Gyr Falcon's survival is uncertain. **Knowing that intervention may be necessary someday, we are learning all we can now...**

Our Impact

Over five years, our cameras at Gyrfalcon nests have amassed a collection of 1.5 million photos—the largest photo data set of any raptor study.

In 2017 we published *Applied Raptor Ecology: Essentials from Gyrfalcon Research* to train future generations of raptor biologists and to standardize methods for gathering data. Not only does this simplify comparison of results across borders, it applies universally to any raptor study—not just Gyrfalcons.

In our fifth year of fieldwork on Alaska's Seward Peninsula, we added another graduate student to increase our knowledge and data on breeding Gyrfalcons.

In 2018 our valued partner, Alaska Department of Fish and Game, helped secure a new pickup to replace our old field vehicle, which was failing us. Now with two vehicles in our fleet, we plan to start large-scale prey surveys in 2019 and 2020.

Fascination with Gyrfalcons is deeply rooted in The Peregrine Fund's history: Tom Cade, our founder, was among the first to publish research about them. Later, our long-term studies in Greenland revealed new information about the species. As climate change concerns began to mount, we already had the unique expertise, partnerships, and data to address the unknown. We hosted an international conference in 2011, then convened the Tundra Conservation Network to connect partners from all eight Arctic countries and multiple disciplines.

Collaboration is vital for saving this species, which has been studied in isolated pockets for centuries thanks in part to the Gyrfalcon's popularity with falconers. We launched the Polar Raptor Databank in 2017 to collect historical and new data in a secure repository, and concurrently published *Applied Raptor Ecology*, a manual that sets standards for gathering comparable, high-quality data. From

anywhere in the world, researchers can now record unlimited observations and access real-time analysis tools. As data are accumulated and shared, ecologists can then answer questions about global population trends and identify factors that have the greatest impact on Arctic raptors.

Our fieldwork is contributing surprising findings to this body of work using motion-activated cameras at Gyrfalcon nests on Alaska's Seward Peninsula. Observing prey items in the photos, we have found that Gyrfalcons rely heavily on ptarmigan, but also adapt their diet when ptarmigan numbers decrease. Cameras documented one female Gyrfalcon moving her young out of a falling nest and carrying it to a new location. We also met some "visitors" to the nests, including grizzly bear, red fox, wolverine, and ravens.

Our fieldwork will continue long-term, as will collaboration with researchers worldwide who are invited to a Symposium on Arctic Raptors at our headquarters in 2020. Ultimately, we will synthesize all shared knowledge about Gyrfalcons into an adaptive management plan to energize conservation action around the world. Acting on sound science, together we will be the difference between survival and extinction for this icon of the Arctic.

01/2019

Andean Condor

Sebastian Kohn

Harold Stiver

With its more than 10-foot wingspan, a soaring Andean Condor is truly magnificent. The ancients depicted it in art more than 4,000 years ago, and five modern countries revere it as a national symbol. But despite its cherished status, this majestic New World Vulture species is declining throughout its vast range from Colombia to Tierra del Fuego, and the northernmost populations are Critically Endangered.

Like other vultures around the world, Andean Condors are often at odds with changes in human customs. Our research is pointing out ways...

Our Impact

In 2018 we worked with Ecuadorian officials and organizations to conduct the second national Andean Condor census, using 100+ points from tagged condors tracked by satellite to reveal population size and trends.

Our data and advice are helping protect a 33,733-hectare area of condor habitat in southern Ecuador. This new reserve is based on spatial data from one condor (Chunka) marked with a satellite transmitter. Our data is also helping create a second reserve near Cuenca, the main city in southern Ecuador.

At 13 known nesting sites we monitored, four pairs showed breeding activity. One nest succeeded; the nest failures appear to be from natural causes.

We have taught census, monitoring, surveying, and field techniques to 194 park rangers from Ecuador's Ministry of Environment and 1,369 officials from other institutions, along with volunteers.

We created Fundación Condor Andino to conserve Ecuador's Andean Condors and other biodiversity.

Several thousand Andean Condors were reported in Ecuador a century ago, but today we know of just 100. **Fortunately, our efforts show that it's not too late:** since 2012 we've found 14 nests, compared to the single nest that had been monitored prior to our study. We gained a wealth of data (left) from nine telemetry-tagged birds, which will help justify immediate conservation measures. Of 31 condors whose blood we tested, all were in good health. And we learned

Condors in Ecuador forage mainly on ranches (red), where clashes with humans are most likely; 90% of nest sites are on private property.

that inbreeding has not occurred, thanks to gene flow between two sub-populations.

The most significant threats are from ranchers who shoot or poison condors in the belief that the birds attack cattle. Although hungry condors have been known to occasionally kill young calves, our studies show they prefer carrion if it's available. Competition for carrion is stiff, however, because of feral and free-roaming dogs. Lead exposure may be another threat; we found high levels in condors from Argentina.

These factors are compounded by the species' naturally slow reproductive rates. Andean Condors need at least seven years to mature before they mate, after which successful pairs only raise a single chick every other year. Productivity can't keep pace with mortality, making the population extremely vulnerable.

Hernan Vargas

The Andean Condor has advantages that bode well for its recovery. Residents and tourists in South America are genuinely interested in saving this cultural treasure, and we've reached millions in documentaries and with a new Spanish-language website (investigacioncondorecuador.com). We partner with Ecuador's Ministry of Environment, and lead the Andean Condor Conservation Network, a continent-wide research consortium.

In time, we hope to preserve habitat for the Andean Condor that will also protect key watersheds and maintain the biodiversity of the Amazon Basin, fulfilling this species' ancient role in Andean myth as a symbol of health and immortality.

Yawar Fiesta—deadly to Andean Condors

Cecilia Larrabure

Cecilia Larrabure

Every July, villagers in southern Peru celebrate independence from Spanish colonial rule. Known as Yawar Fiesta or “Blood Festival,” the event attracts tourists to witness a life-or-death struggle: a wild Andean Condor, symbolizing the Inca people, is tied on the back of a bull representing Spain. A matador then goads the two frightened animals into a bloody fight.

Andean Condors are already in steep decline. This long-lived bird, an icon of Peru’s cultural heritage, urgently needs protection...

Our Impact

We partner with Centro de Ornitología y Biodiversidad (CORBIDI) and the Peruvian Forest Service (SERFOR), both of whom are committed to eliminating the negative impacts of Yawar Fiestas on Andean Condors.

In 2019 we hope to provide grants to two students and recruit volunteers to find, document, and film Yawar Fiestas, trapping locations, and treatment of the condors. Footage will be used to create short documentaries.

Our plans include conducting a pilot program in three communities, providing teacher training and educational materials for students of all ages. Our message will focus on the importance of condors in Andean culture and folklore, as well as protection of the species.

We'll engage local leaders as well, and train police to safely deliver injured Andean Condors to authorized rehabilitation centers.

We don't yet know how many villages hold Yawar Fiestas, but current estimates suggest that 60 wild Andean Condors are trapped every year for the spectacles. The birds are typically kept in unsafe conditions for several days, paraded through the streets, and fed alcohol before the main event. Those that live through the ordeal are released, but it's unknown whether they survive or for how long.

Although Peruvian law forbids the capture of wild animals, the festivals are carried out under the leadership of local mayors, police, and priests. Peruvians revere the Andean Condor as sacred, symbolizing a god descending from the heavens to fight on their behalf. **Most are not aware that the ritual harms or kills the condors.** And with the enticement of tourist money, we believe the number of communities hosting Yawar Fiestas is growing.

Cecilia Larrabure

Our data from Ecuador and elsewhere shows Andean Condors already in decline, poisoned or shot primarily by ranchers in retaliation for livestock deaths. Although condors feed mostly on carrion, they are able to occasionally kill calves. **Since Andean Condors only raise a single chick every other year, losses related to Yawar Fiestas are simply not sustainable.** Condors fly vast distances, and it's likely that the toll from Yawar Fiestas affects the entire population, which ranges from Colombia to Tierra del Fuego. Our immediate task is to determine how many festivals take place, and the impact they have on the species as a whole. Our partners, staff, students, and volunteers are poised to do the necessary fact-finding by attending numerous fiestas to observe, document, and film.

With this information in hand, we hope to influence local officials and train them to protect Andean Condors. We'll also design and launch an outreach program appealing to Peruvians' desire to protect their cultural heritage and respect condors, while offering a new perspective about the species' precarious existence. We'll conduct a pilot program in three communities, evaluate the effectiveness, then adjust as needed and expand throughout the region until we achieve **our goal: ending the trapping of Andean Condors for Yawar Fiestas.**

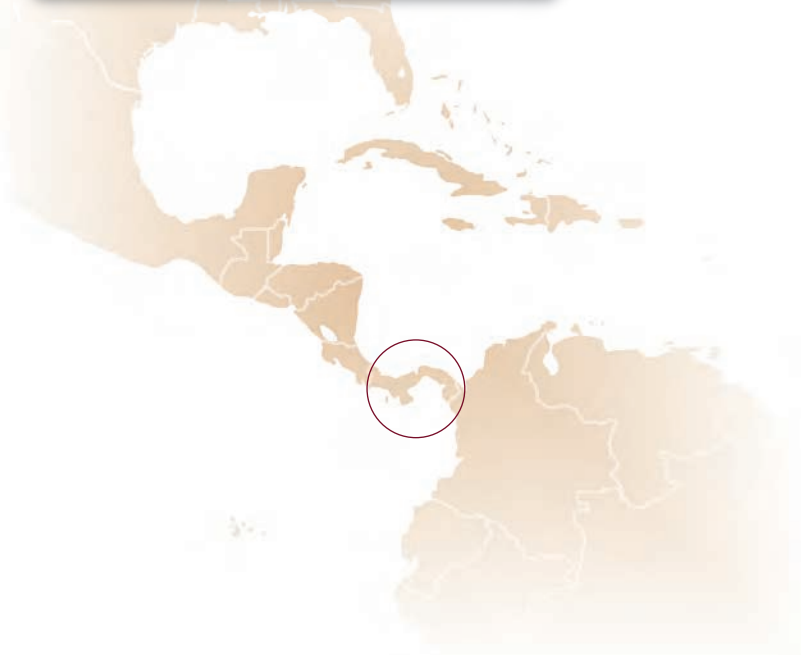

Harpy Eagle

David L. Anderson

Jose Vargas

With their long, curved beaks and talons the size of grizzly bear claws, Harpy Eagles are the largest and most powerful eagles in the world. These commanding birds swoop through the rain forests of Latin America, routinely picking up prey weighing more than 15 pounds—and sometimes equal to their own weight.

As Panama’s national bird, the Harpy Eagle is a “flagship” species—an emblem of a fragile ecosystem whose fate depends on us...

Our Impact

Since 2000 we have found and monitored 56 nest sites in Panama. In 2017, five previously unknown nests were reported to us by local people.

Near 90% of the known breeding pairs did not breed last season, indicating low productivity in this long-lived species.

Harpy Eagles prefer pristine, mature forest for nesting. Our tracking data allow us to pinpoint those areas for conservation.

More than 2,000 people attended the annual Harpy Eagle Festival, which we began years ago to educate the public. One of the main threats to the species is people shooting eagles. Continued outreach is crucial as new people move into the region.

01/2019

Harpy Eagle mortality

Human-caused: 46%

Natural: 54%

Although Harpy Eagles maintain healthy populations in South America, **the outlook is troubling in Central America, where in most countries they are listed as Critically Endangered.** New roads, slash-and-burn farming, and forest fires threaten to destroy intact rain forests that are crucial to their survival.

The largest known population of Harpy Eagles in Central America is found in Darien Province, Panama, where The Peregrine Fund has been working since 2000 on one of the longest projects ever conducted for the species. Our insights into breeding, dispersal, habitat, diet, and causes of mortality are pivotal in mapping the future of this long-lived, charismatic eagle.

We haven't worked alone, though—for 18 years we have partnered with local communities in our Darien work. Every year we train Emberá and Wounaan technicians and volunteers who not only conduct fieldwork and help us mount transmitters (below), but also spread the word within their communities about the value of Harpy Eagles. Emberá and Wounaan people have inhabited the Darien for time immemorial, and their ability to manage development from outside forces is essential to preserving their homeland along with the eagles' habitat. Our support for the people of Darien is crucial, and assisting with sustainable jobs and education is an integral part of our conservation approach.

Arillo Ismare

As the first organization to ever establish a program to breed Harpy Eagles in captivity and release them to the wild, our familiarity with the species is unmatched. But we have more to learn to conserve the Harpy Eagle in the chaotic years ahead. We need to understand the degree to which various types of human disturbances affect the eagles' ability to hunt, establish territories, and reproduce. If factors like habitat fragmentation, tourism, agriculture, and road building limit the population size, **we must have solid data to advocate effectively for preserving this high-demand landscape.**

Our newly-launched Darien Conservation Initiative, which aims to preserve four million acres of rain forests in Panama, is firmly grounded on the relationships we've cultivated for nearly two decades of studying and conserving Harpy Eagles.

Saving Rain Forest for Humans and Harpy Eagles

Darien Conservation Initiative

Jose Vargas

David L. Anderson

Deep in the innermost reaches of Panama, on the border with Colombia, lies the Darien Gap—the largest and wildest remaining stretch of rain forest north of the Amazon. Indigenous peoples have lived traditionally in the area for millennia, and the largest population of Harpy Eagles in Central America nests in the forest's towering native trees.

Situated on the bridge between North and South America, the Darien and its inhabitants are at geographic and historic crossroads. **By blending their traditional values with sustainable modern livelihoods we will empower them...**

THE PEREGRINE FUND

Our Impact

We established the Darien Initiative in 2018 to develop sustainable economic actions that raise local revenue and reduce forest disturbance and degradation from agriculture and hunting.

Twelve families in two communities engaged with us and reached 900 people in seminars.

We are assisting the indigenous Emberá and Wounaan people in creating associations to maintain control over their lands. In the past 18 years we have employed 35 local people in the field to conserve Harpy Eagles, and supported the formal education of more than 55 students.

In 2017, we assisted in building aviaries to raise chickens in four communities; in two communities we built nurseries where 1,500 native tree seedlings were planted.

Panama's Ministry of the Environment is a trusted partner, thanks to our long-term Harpy Eagle work and the reputation we've earned as researchers in Central America since beginning the Maya Project in 1988.

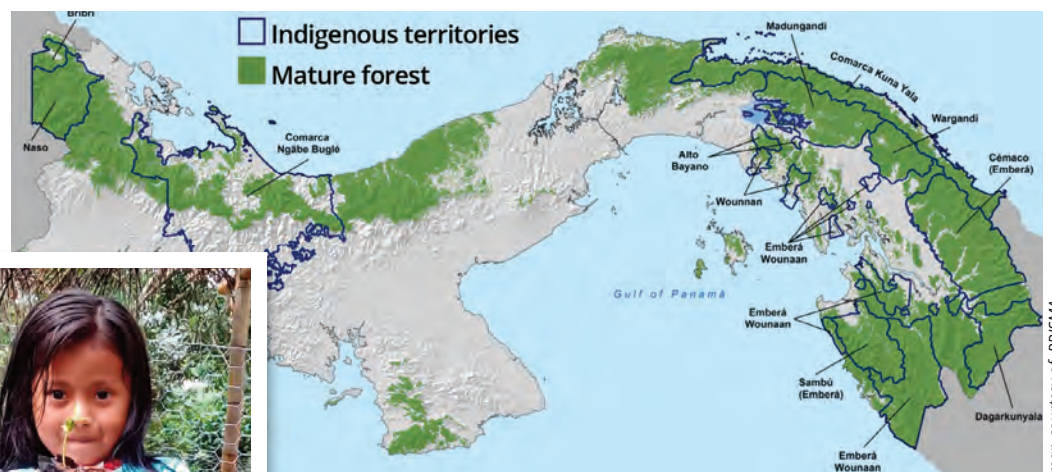

The Darien region, though roughly the size of Connecticut, is home to more than 500 bird species—54 of them raptors. With a fifth of its plants found nowhere else and the potential for many more species to be discovered, **Darien is one of the most biologically rich places on earth—a biodiversity “hotspot.”**

We have studied the threatened Harpy Eagle in Darien since 2000, when we also established Panama's first non-governmental organization for raptor conservation. For many years, we also raised and released Harpy Eagles and conducted public education and outreach in Panama, and our studies on wild populations are ongoing. Our friends throughout the country provide us an intimate understanding of the complex pressures on the Darien and its inhabitants. Now, we are prepared—together—to meet an accelerating threat: land development.

As decades-long conflict in neighboring Colombia comes to a peaceful end, forces are organizing to develop Darien. *Colono-campesino* land invasions, slash-and-burn agriculture, and uncontrolled cattle ranching are cutting into the forest. At the same time, indigenous Emberá and Wounaan communities are entering the 21st century cash economy, abandoning traditions that have allowed their coexistence in native ecosystems, and adopting unsustainable farming practices.

Ariño Ismare

map courtesy of PRISMA

To meet these challenges, we are creating economic incentives that encourage forest preservation and improve access to education. These initiatives meet human needs and protect the rich biodiversity of Darien.

For example, **soon we will expand and improve shade-grown coffee plantations to support jobs that don't harm the rain forest.** We already assist with chicken coops and plant nurseries to provide food and discourage the hunting of bush meat.

We pioneered community-based conservation nearly thirty years ago in Madagascar, also a biodiversity hotspot. So far, we have helped 11 communities there organize to manage local resources, expanded the country's national protected areas by more than a million acres, and supported the education of hundreds of people as conservation leaders. Our experience of “saving raptors, enriching lives” at various scales around the world gives us high expectations for Darien.

Orange-breasted Falcon

Robert Berry

Above: Transported to Belize by private charter, four fledgling captive-bred Orange-breasted Falcons are placed in a hack box, cared for by attendants and a resident pair of adult falcons prior to independence in the fall.

Right: 2010 released captive-bred male B1, superstar of The Peregrine Fund's restoration project in Belize, attracted a wild mate at the hack site and produced seven young before disappearing in 2017. He was replaced by his son P29.

Robert Berry

Always rare and widespread because of its specialized habitat requirements, the Orange-breasted Falcon now occupies only four percent of its historical range in Central America, limited to the Maya Mountains of Belize and along the Mirador Cordillera in Guatemala. Our surveys disclose that despite large areas of apparently suitable habitat, this falcon's numbers are in steep decline with fewer than 20 territorial pairs remaining now isolated by 1500 km from a few pairs in the Darien of Panama and the little-known population in South America.

If current trends continue, extinction of the remaining Central American population may occur in less than a decade. As the only captive breeder of Orange-breasted Falcons, we are poised...

Our Impact

In 2018, an incomplete year because of injuries, we surveyed only 15 of the 32 historic territories in Belize and Guatemala. Ten were occupied, and at least three fledged young. We have banded 52 wild nestlings since 2007, which along with captive-bred released progeny help us monitor the population.

Our hack site includes the first-ever artificial nest box occupied by a nesting pair of falcons that help feed and protect the hacking juveniles. High turnover among these resident adults and current occupancy by a locally-banded wild male and a female fledged from Tikal Park, 55 miles away, highlight the lack of recruitable adult falcons.

We released 56 captive-bred falcons since 2007, six this year, all of which fledged successfully. We provided a visually challenged (and therefore unafraid) female OBF to our partner, Belize Raptor Center, that has become a key ambassador for education and outreach.

Despite our efforts to bolster and add genetic diversity to the small Central American population, decline continues as mortality outpaces productivity.

Our large, widely-distributed poster, along with educational programs and citizen science reporting, show that we are changing the culture in Belize away from viewing raptors as vermin, with a goal to end persecution of all raptors.

Orange-breasted Falcons appear to have unique survival advantages: they nest on towering cliffs in rugged and remote mountain habitat that they occupy year round. They care for their young three times as long as other falcon species. They have potentially long reproductive lives of 10 or more years, similar to other falcon species, but a much lower reproductive rate, and our recent banding studies indicate that **the life expectancy of an adult Orange-breasted Falcon is just 2.57 years.**

Help save the Orange-breasted Falcon!

The Orange-breasted Falcon is a rare and beautiful tropical gem, vital to Belize's birding tourism and economy. Only a few dozen pairs remain in Central America, mostly all nesting in the Maya Mountains of Belize. The Mountain Pine Ridge is one of a few places in the world where you can see them.

Please help us change the prejudice against birds of prey. Hawks and falcons benefit people by controlling large numbers of rats and mice. Orange-breasted Falcons winter in lowland rural communities and cities like San Ignacio and Belopan feeding on increasing numbers of pigeons captured in flight. Falcons do not get and animals or chickens but often pay with their lives as they are unafraid of humans and easily killed!

The Peregrine Fund has monitored the falcon's decline for three decades and we are helping save them by releasing captive-bred birds into the wild [see Living Bird, article for more information].

WE NEED YOUR HELP!
This spectacular falcon is declining because of illegal shooting!
We are losing the battle to save them!
WHAT CAN YOU DO?

1. Please tell your friends and family not to shoot beneficial hawks and falcons, but to enjoy them as thousands of birders and tourists do in Belize.
2. Contact a birding friend to help you see an Orange-breasted Falcon.
3. Report your sightings (band color and number if banded) to eBird.org

What are we doing?

Research
 Above: Clamber banding young Orange-breasted Falcon (Peregrine Fund) and Belize Raptor Center. Below: Color banding with location number to provide survival information, which along with surveys of other nest sites enable us to predict current declining population and reproduction risk.

Captive Breeding
 The Peregrine Fund maintains the only captive Orange-breasted Falcon captive breeding colony in the world. We have raised 44 falcons in Belize in the past 10 years. The sequence of events includes the breeding from the adult falcons and their chicks and the youngsters "going to Belize" the following day.

Released and Free
 Photos of the birds' home territory in the remote Mountain Pine Ridge, capture band chicks wearing the new color on the back and fledging, playful social contact to have hunting skills, and support care and food (B) and wild care behavior in the wild (C) following an offspring since 2013. The pair helps feed and protect both wild and captive-bred progeny along with our hack site steward.

STILL IN PROGRESS

Read more about the project in Living Bird, Fall 2014 at bit.ly/488falcon

The cover photo features a pair banded Orange-breasted Falcon female, one of the females (pigeon) produced by captive-bred male (B) and a wild female.

We believe the cumulative effects of habitat alteration, fragmentation, human conflicts, and natural predation together help explain the large diminution in the species' range and continuing local decline. We can confirm that this once mountain species now leaves the sanctuary of its mountain home to hunt invasive feral pigeons and collared doves in the surrounding lowlands and cities, where all raptors are persecuted as vermin.

To help bolster this small declining northern population, each spring we conduct an arduous three-month long hack of captive-bred juveniles bred at our Wyoming facility—no small feat, since this species has proven to be the most difficult of falcon species to breed in captivity. Despite unforeseen high mortality, our captive-bred birds and their progeny are now breeding with wild mates, designed to increase genetic diversity, fitness, and future productivity.

DNA analysis of blood samples from the Orange-breasted Falcon's entire range is underway at the University of Wyoming, and we're partnering with Cornell's eBird to create models, map habitat, and help identify relatedness, population status, and guide future research.

We search for new pairs while monitoring known territories both on foot and by helicopter, including in the Darien region of Panama, a biodiversity "hotspot" where we also conserve Harpy Eagles. We plan to assist Darien's local communities to **create economic alternatives to forest destruction, benefiting raptors and numerous other species including the Orange-breasted Falcon.**

Puerto Rican Sharp-shinned Hawk

Russell Thorstrom

Even before Hurricanes Irma and Maria, the entire recorded population of Puerto Rican Sharp-shinned Hawks was just 75 individuals in the 2017 breeding season. We feared the worst after the hurricanes in September, wondering if any bird could survive sustained winds of 155 mph.

Sifting through the remains of the flattened forest, we found a small miracle: at least 19 Sharp-shinned Hawks survived. With few nest trees remaining and very little prey, we mounted a rescue mission...

Our Impact

Puerto Rican Sharp-shinned Hawks have been on the U.S. Endangered Species List since 1994. We surveyed annually beginning in 2015. Prior to the Category 5 Hurricane Maria in 2017, we observed 75 individuals in four locations, all in forests above 750 m elevation.

After the hurricane, we found 19 individuals—a decline of 75%. Six pairs nested; of those, we left half unmanaged and pulled eight eggs from the other half to incubate safely in our lab. We raised six young and released them at a hack site we built—The Peregrine Fund's first-ever release of an Accipiter.

Of the three unmanaged pairs, only one was successful, raising two young to fledging age.

Puerto Rican Sharp-shinned Hawks don't migrate, nor are they found anywhere beyond their island stronghold, in habitat depleted by human land use. The hawks depend entirely on the dense mountain forests of this Caribbean island for nesting and hunting. Like Sharp-shinned Hawks on the American mainland, they are agile fliers, but they're smaller and have brighter plumage.

Hurricane Maria decimated the forests, actually stripping the leaves off the relatively few trees left standing. The majority of mature trees were blown down, uprooted, or snapped off, leaving only palm trees and tree ferns. Without foliage, nestlings don't have shelter from heat, rain, or predators. Given the scale of devastation in Puerto Rico, we estimate full recovery of the forest could take up to 20 years.

Russell Thorstrom

Even adult birds are subject to starvation because their main prey—small birds like tanagers, warblers, and vireos—also depend on adequate forest habitat. With such difficult conditions, our first act was to provide supplemental food so the remaining Sharp-shinned Hawks could become healthy enough to breed.

As eggs appeared last spring we carefully moved some into incubators to hatch in a secure, climate-controlled breeding facility on the island. Since these hawks normally produce a second set of eggs if the first set is lost, we were able to raise chicks in the safety of our facility without compromising the wild parents' success. We raised and released six young as the wild pairs raised only two.

Few organizations have the expertise or resources to respond to an emergency of this scope, but The Peregrine Fund has returned numerous raptor species from the brink. We expect to learn a great deal in Puerto Rico and have already achieved a new milestone with our first-ever release of an Accipiter. This rescue operation will hone our skills for a future of extreme weather and ever more threatened island species.

01/2019

Ridgway's Hawk

Thomas Hayes

When The Peregrine Fund began investigating the Ridgway's Hawk, only about 300 remained. This charismatic species' habitat was lost to human development, restricting the remnant population to the small Los Haitises National Park on the northeastern coast of the Dominican Republic. A single forest fire, virus, or hurricane could have caused its extinction in the blink of an eye.

A closer look revealed a daunting collection of threats, requiring us to dig deeper than ever for creative solutions...

Our Impact

In 2018, we recorded 134 pairs of Ridgway's Hawks raising 142 young in Los Haitises National Park. We located 19 wild pairs of hawks in the released population at Puntacana Resort. Since 2013, 32 wild-hatched young have fledged at Puntacana.

We trained six new volunteer field technicians, raising our local workforce to 23.

We reached close to 1,700 people through school presentations, teacher and youth training workshops, and door-to-door visits in 20 communities.

More than 280 people attended Ridgway's Hawk Day activities in two communities. These include the first annual Ridgway's Hawk Day Fair, held in conjunction with the Punta Cana Farmer's Market, and visits to the Punta Cana release site by more than 70 students and teachers.

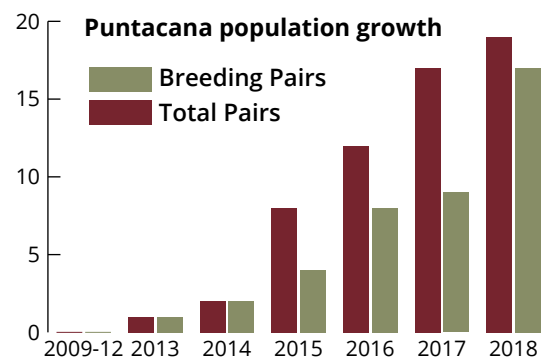

Habitat loss was just one of the many threats impacting Ridgway's Hawks. They were also being shot by people protecting their chickens. To make matters worse, botfly infestations frequently killed nestlings, resulting in reproductive rates that could barely sustain this fragile population.

This "perfect storm" of threats called for an equally perfect storm of innovation. We began by testing a technique called *assisted dispersal* to effectively "transplant" young hawks to new, safer territory and expand the species' range. At the same time, we informed residents in both areas that the hawks typically eat reptiles and small rodents — not chickens — and offered free cages to protect young poultry from all predators. Our school visits, printed field guides, and media interviews are changing attitudes towards Ridgway's Hawks and other raptors. We also hire and train residents as field technicians, and purchase locally-made handicrafts to offer in our gift shop, effectively stimulating the local economy while showing how conservation benefits birds *and* people.

Marta Curti

Once we knew assisted dispersal could work, we discovered a new problem: electrocution by power lines. We quickly partnered with the local utility company to retrofit power poles surrounding the new territory at Puntacana Resort and Club, where our "transplanted" population now thrives. The Grupo Puntacana Foundation promotes ecotourism and conservation programs, directly benefiting hawks.

Botfly infestation is a more complex problem, but at nests where we applied a pesticide, **nestling survival rates increased more than four-fold.** This intervention is crucial for restoring the Ridgway's Hawk population while our researchers look for the causes of this ecological imbalance. Botflies are an emerging threat to species throughout the Caribbean, and our discoveries now will contribute to future conservation needs.

African Vultures

Percy Mitchell, oocphotography.co.za

Munir Virani

More than any other continent, Africa is known for its circle of life revolving around massive herds of migrating animals hunted by fierce predators. Vultures are critical to that circle as efficient “eco-janitors.” Without them, diseases like rabies go unchecked, and the price is high—as demonstrated by a surge in human rabies deaths since south Asia’s vulture populations began to crash in the 1990s.

Vulture numbers across Africa have plummeted for over three decades. Against a backdrop of development, poaching, and poisoning incidents, we are racing...

Our Impact

More than 1,050 people in Kenya have received our training. Tens, if not hundreds, of vultures and other scavengers have been saved by trainees who averted the poisoning of two lion prides.

Our coexistence training tackles human-predator conflict by teaching people how to build predator-proof corrals, or bomas, that keep livestock safe.

Our new WhatsApp group, the Vulture Protection Network, connects nearly 50 individuals we trained in wildlife poisoning intervention. Instant messaging alerts them to poisoning events and conflicts, enabling more rapid decontamination and sample collection. The group has prevented secondary poisoning by responding to poisoned carcasses of lions and hyenas. Since the poisoning of 45 vultures in February 2018 in the Masai Mara, our network has ensured that the number of vultures poisoned is down by more than 50 percent.

As demand for power, food, and material goods escalates throughout Africa, The Peregrine Fund has risen to meet new threats to vultures. Chief among them is wildlife poisoning. Livestock owners use poison to target predators like lions and hyenas, inadvertently killing vultures and other scavengers. Poachers deliberately kill vultures to avoid having their crime scene exposed by circling birds.

In 2018 we began *The Coexistence Co-Op*, a collaborative project with Lion Landscapes to reduce poisoning and the human-predator conflict that triggers it. We conduct community-based coexistence trainings to raise awareness about the dangers of poisoning and to teach locals how to build predator-proof bomas (corrals). One of our trainees helped to save a girl's life when poison was used to attempt suicide. **Our project in the Masai Mara has reduced vulture poisoning by over 50%.**

We have collected poisoning data since 2005 and collaborated with the Endangered Wildlife Trust to create the African Wildlife Poisoning Database, which has recorded 272 poisoning incidents in 15 countries, and the deaths of more than 8,000 animals of 40 different species. **However grim, this data-gathering is the crucial spark for funding and action.**

Darcy Ogada

We also tag and track vultures (left). Not only are we learning where vultures are likely to encounter poison, our data are also valuable to energy developers for the proper siting of new wind farms. Vultures are among the few

bird species for which tracking data are available in Kenya, giving conservation a scientific, credible voice on this rapidly-changing continent.

Another outstanding example of data-driven results is the African Raptor Databank (ARDB), a smartphone app used to record raptor sightings. Since 2014, ARDB has amassed more than 200,000 records from 38 African countries. ARDB documented declines of up to 80% in eight of Africa's 10 vulture species, justifying their uplisting to Endangered or Critically Endangered. **The status upgrades sounded the alarm internationally, prompting organizations to redirect funds and staff.** This shared databank concept now serves as the basis of our Global Raptor Impact Network, so we can assess all raptor species worldwide.

01/2019

Madagascar

Lilly-Arison Rene de Roland

Islands are some of the most richly-diverse places on Earth, home to life evolved in isolated, unique habitats. Madagascar, the world's fourth-largest island, boasts 310 bird species in an area the size of Montana and Idaho combined. More than half of those species are found nowhere else.

The Peregrine Fund went to Madagascar in 1990 to search out rare, endangered birds of prey, and we found them—even some that were thought to be extinct.

To conserve those species, we had to devise radical new ways of empowering local people...

Our Impact

In 2017, one of our three community conservation areas, Bemanevika, was the third to be recognized as a Ramsar site—a wetland noted by the United Nations as significant “not only for the country... but for humanity as a whole.”

Among our three conservation areas, we have assisted communities in planting more than 215,000 saplings to restore forests and establish plantations for food and jobs.

We have fostered an educated, professional staff of more than 30 Malagasy people, many with advanced degrees. They contribute scientific knowledge and lead their communities in conservation.

With nearly 30 years proving the concept in Madagascar, we're ready to transplant community-based conservation to the Darien region of Panama—another vital biodiversity hotspot where indigenous communities have a vested interest in conservation.

Like its neighboring island of Mauritius, where we had helped restore the Mauritius Kestrel from just four survivors, Madagascar had a wealth of diversity but little infrastructure for understanding or protecting it. Of the 24 raptor species on the island, 14 are endemic—found nowhere else—and of these, two had not been seen for more than 60 years. Our biologists re-discovered both, plus a missing duck species, and even found four previously unknown lemur species!

Discoveries are thrilling, but preserving species in perpetuity is a complex undertaking. Habitat alone is not enough; human pressures call for human vigilance, and **this realization, reinforced by our success, resulted in a rapid paradigm shift for conservation worldwide.**

Our early insights came from people living near degraded wetlands where we found Madagascar Fish Eagles struggling to survive. Sustainable village traditions were being violated by newcomers, and residents could protect neither their own livelihoods nor the wildlife. **We helped form the first local association in Madagascar with legal authority to enforce limits on resource use.** Under a new federal law, the community was empowered, the eagle population stabilized, and today those wetlands are a pristine habitat supporting wildlife and people.

Lily-Arison Rene de Roland

Working with local associations keeps raptor conservation at the forefront. For example, we supply fiberglass canoes so that fishermen no longer make dugout canoes from mature trees, preserving choice nest sites. We distribute special fishing nets, reducing the use of nets that ensnare and kill fish eagles. Reforestation projects provide food for people and habitat for wildlife. Community wells, hydroelectric power, eco-tourism, honey production, and schools are all made possible by our simple philosophy of “saving raptors, enriching lives.”

We now work with 11 local associations close to our raptor conservation sites, and the benefits reach beyond individual villages; **together, we have added almost a half million acres of habitat to the country's National Protected Areas**—equal in size to Great Smoky Mountain National Park in the United States.

Asian Vultures

Munir Virani

Vultures are masters at scouring the landscape to quickly pinpoint fresh carcasses—a critical food source for them, but a bacteria-laden hazard to humans. Vultures’ adaptations—high stomach acidity, crushing bill strength, and featherless heads for staying clean—guarantee efficient clean-up, so disease-spreading scavengers like rats, feral dogs, and flies don’t multiply.

From the mid-1990s, vulture populations throughout south Asia crashed, with up to 99% of some species literally dropping dead without explanation. Finding the cause was grim, difficult work, but we persisted...

Our Impact

In 2003 we discovered the cause of millions of vulture deaths: diclofenac sodium, a non-steroidal anti-inflammatory drug used for ailing cattle.

That year we opened the first vulture “restaurant” in south Asia to provide diclofenac-free food. Several have since been established by communities who value vultures and benefit from tourists who come to see them.

Nepal, India, and Pakistan banned the drug for veterinary use, thanks to our findings and advocacy with partners: the Bombay Natural History Society, the Royal Society for the Protection of Birds, Nature Conservation Pakistan, and Bird Conservation Nepal.

As part of Saving Asia’s Vultures from Extinction (SAVE), a consortium of organizations, we annually measure conservation impacts at vulture breeding colonies in India.

Three vulture species in Asia were destined for extinction in less than a decade, a catastrophe unprecedented since the loss of billions of passenger pigeons in the last century. Peregrine Fund biologists struggled to understand how tens of millions could die so rapidly, and through meticulous forensic investigations discovered the answer in 2003: an inexpensive, readily-available drug called diclofenac sodium had been introduced in the region for treating sick cattle. Consuming even small traces of diclofenac in cattle carcasses causes rapid kidney failure in vultures. Since only four percent of an estimated 500 million cattle in India are for human consumption, the availability of carrion for scavengers is significant.

The Peregrine Fund advocated along with conservation and government partners to ban veterinary use of diclofenac in Nepal, Pakistan, and India, and bans

were enacted three years later. To measure the bans’ effects, we monitor 450 pairs of Long-billed Vultures in the Indian states of Madhya Pradesh and Rajasthan. The population stabilized in the five-year period after the ban was enacted, leading us to believe a positive trend had begun; but **more recently we’ve observed declines, pointing to a need for vigilance and further action.**

Simon Thomsett

Diclofenac is still available for humans, and can easily be misused for treating livestock. At least seven other veterinary drugs on the market are potentially toxic to vultures, and new drugs may appear without thorough testing. We work closely with partners in south Asia who are identifying vulture-safe alternatives and encouraging tighter regulation of toxic veterinary drugs. We also track 13 Bearded Vultures (photo above) to study their habits and territories, and we support graduate students throughout south Asia to increase our capacity to deal with future crises.

In 2017, the **United Nations Convention on Migratory Species** recognized The Peregrine Fund in a Raptors Memorandum of Understanding. The Convention seeks to halt population declines of 15 vulture species across Africa and Eurasia and recommends 124 actions for countries to restore numbers by 2029.

Education at the World Center for Birds of Prey

Jeffrey L. Armstrong

Erin Katzner

The World Center for Birds of Prey is the heartbeat of The Peregrine Fund's education program. Situated in one of the most densely populated raptor regions in the world, it is an international destination for 50,000+ people a year. Visitors experience raptors up close and personally through live, daily raptor demonstrations and interactions with staff, volunteers, and exhibits that create a deeper understanding of these incredible birds and our role in conserving them for future generations.

We're influencing people's attitudes, emotions, knowledge, and behaviors about raptors and wild places....

Our Impact

The World Center for Birds of Prey engages more than 50,000 people annually, and has become a top-rated attraction in Idaho.

Over 7,000 guests come nose-to-beak with hawks, falcons, and owls that swoop inches overhead during Fall Flights, an annual sold-out event and family tradition for visitors throughout the region.

The Center provides free school tours for more than 4,000 students annually, engaging students in STEM learning focused on the scientific method through the lens of our global conservation projects. Teachers rate our program 4.9 out of 5 for overall satisfaction.

In 2018, 145 volunteers contributed more than 11,000 hours of service, valued at over \$242,000.

Center programming would not be possible without generous community support from Laura Moore Cunningham Foundation, Idaho Power, Albertsons, U.S. Bank, and other generous individuals and businesses.

The Peregrine Fund's vision is to create a world where birds of prey are valued by all humans. Our Visitor Center serves as the foundation for empowering guests to save raptors and find solutions that protect wild places we all need for survival.

At the World Center for Birds of Prey, visitors come nose-to-beak with raptors from around the world while learning about conservation work. The Peregrine Fund leads on a global scale to save each species. When people have the opportunity to experience one of our avian ambassadors up close, an emotional connection can form that changes attitudes toward conservation in a positive way.

The recovery story of the Peregrine Falcon is one of the greatest conservation success stories of all time. It is a story of people coming together to tackle an environmental problem that affects us all. **The message is clear—we have the power to save species when we work together.** The World Center for Birds of Prey has shared this empowering message with nearly one million visitors since opening its doors in 1994.

As we approach our 50th anniversary in 2020, The Peregrine Fund has renewed its commitment to education and public engagement. The World Center for Birds of Prey is expanding its footprint to showcase our international conservation work in partnership with local communities and increase exposure to native raptors and conservation efforts that promote coexistence between humans and the natural world, with wise stewardship of the land.

To learn more about our educational expansion, please contact Heather Meuleman, Campaign Director, at hmeuleman@peregrinefund.org or 208.362-8240.

Global Engagement

Nyambayar Barbayar

Paul Spurling

More than half of all raptor species worldwide are in decline, and the causes almost always point to rapid growth of human populations. To prevent extinction, it's more urgent than ever to inspire, teach, and connect with people of all ages, in every corner of the globe. The fate of raptor species is in their hands.

People value birds of prey and want to protect them, but they need The Peregrine Fund as a catalyst, empowering them...

THE PEREGRINE FUND

Our Impact

Our social media reach now exceeds 100,000 people around the world. Followers see diverse content, from video of California Condor releases to entries in our juried photo competition.

Almost 10,000 people receive project updates in **Notes from the Field**, our bi-weekly e-newsletter.

Live raptors at our World Center for Birds of Prey in Boise, Idaho, greeted more than 50,000 people last year, a new record.

Seven of our projects provided support and training to 41 students in 2018. Twelve graduated with degrees, leading the way toward our goal of **establishing a raptor biologist in every country on earth.** Since 1970, we have supported and trained more than 130 students.

Our reach in the Boise community has expanded significantly through development of new partnerships with other nonprofits, special events to engage citizens, and sponsorships from local businesses.

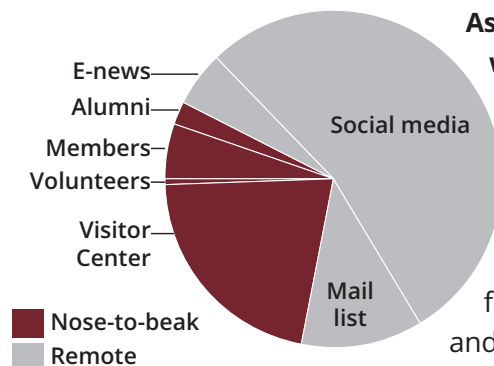

As our scientists have traveled to the far reaches of the globe, we have made important discoveries about birds of prey; but **equally important are fresh insights into human behavior.** We know, for example, that people are intensely curious and sometimes shoot raptors to get a closer look. We have learned that people who come to understand a raptor's role and life history will gladly make accommodations that allow them to thrive. And finally, we've found that when raptors are part of a holistic picture that includes economic incentives — like local jobs, ecotourism, education, or sustainable food — people become champions for birds of prey.

Donatien Randrianjafinasa

Truly empowering people challenges us to reach out in meaningful ways... and **with more than 586 raptor species and billions of people on the planet, our outreach must take many forms.** Face-to-face and “nose-to-beak” interactions are ideal, so whenever possible we let raptors speak for themselves in classrooms and communities near our projects and at our visitor center in Boise, Idaho. When personal contact isn't possible, we count on video, photography, and vivid storytelling to connect people with birds of prey.

Sometimes our outreach doesn't involve a bird at all; instead we provide basic needs like fishing nets, chicken coops, tree seedlings, career training, tuition, and connections to government resources. We call this approach “saving raptors, enriching lives,” because it offers a way to make room for raptors by improving opportunities for people, their communities, and the next generation.

As The Peregrine Fund nears its 50th year, we're reflecting on the millions of lives we've already touched

along the path to conserving Peregrine Falcons, California Condors, and hundreds of other species. Confident that we can again change the future, we're calling on all of our “alumni,” from members to students to birdwatchers and beyond, to support raptors while we can still act to prevent extinction.

Investing in Tomorrow's Conservation Leaders

Gonzalo Igrasi

Alex Ospina

Studying raptors requires a rare set of traits: an obsession with birds, the grit to find and document them in rugged conditions, and the discipline to analyze and publish credible results.

Because conservation hinges on scientific rigor, we seek out and encourage the kind of peer-reviewed, published work taught by universities—but that level of education is not easily accessible to everyone. **Exceptional students around the world need our support in becoming scientists and leaders...**

Our Impact

Since 1970, students receiving our support have earned **116 advanced degrees**, including 28 Doctorates and 88 Master's or equivalent degrees. They have graduated from more than 45 universities in 15 countries.

In 2018 alone, we provided financial and/or logistical support and training to **41 students associated with seven of our projects** from East Africa to Alaska. Twelve graduated with degrees.

In 1987 we helped launch a Master's program in raptor biology at Boise State University, the first of its kind in the world.

We connect students and professionals by providing stipends for travel to international conferences like the Neotropical Raptor Conference. In 2020, we'll bring students from around the world to Boise when we host the Raptor Research Foundation conference.

Higher education is at the very root of The Peregrine Fund; in fact, Cornell University was our first home, established in a breeding barn by Professor Tom Cade when he joined the faculty there in 1970. Academic rigor informs every one of our strategies, and like all teachers **we look for opportunities to nurture students' curiosity, resourcefulness, and connection to a global community.**

Our projects provide invaluable experience for motivated students. In Pakistan, student Jamshed Chaudry has witnessed first-hand the catastrophic decline of the region's vulture species and participated in the recovery efforts. In Kenya, Washington Wachira studied Crowned Eagles and spoke at the prestigious TED

Global Platform (left) on his love of birds. In Argentina, Amira Salom based her thesis on interviews with local people about their perceptions of birds of prey.

With our guidance, students turn field experiences into career-changing results: Dr. Lily-Arison René de Roland was our very first master's-level student in Madagascar and has since completed doctorate and

post-doctorate work, received recognition as a Disney Conservation Hero, and serves now as National Director of our Madagascar project. Dr. Hernan Vargas, director of our Neotropical Science and Student Education program, started with limited opportunities in the Galapagos Islands and got his "big break" with a Peregrine Fund grant to study raptor biology at Boise State University. He now directs the studies of dozens of students throughout Central and South America. With our support, Nyamba Batbayar studied raptor biology at Boise State University and went home to found the Wildlife Science and Conservation Center of Mongolia.

Most students we assist go on to influential positions in their home countries, serving in wildlife management, government agencies, and other non-profits. As local residents, they can navigate cultural norms that might present obstacles to a foreigner. When conservation crises occur, these in-country partners are trained and ready to respond.

Our students are so valuable to the future of raptors that we've formalized our mentoring plans with **one audacious goal: to establish a raptor biologist in every country in the world.** We're focusing on Africa and South America because of their fast-growing economies and high demand for education. Threats to raptors and other biodiversity are rapidly increasing on both continents, meaning our students' impact is likely to be significant and long-lasting.

Almost 50 years ago, our founders resolved to save Peregrine Falcons from extinction. Their life's work is a legacy we all enjoy each time we glimpse one of these magnificent birds in the wild.

The Peregrine Fund's planned giving society

You, too, can give the gift of raptor conservation by including The Peregrine Fund in your estate plans. You will join a special group of donors who receive permanent recognition at the World Center for Birds of Prey in Boise, invitations to special events, and recognition in the annual report (unless you wish to be anonymous).

Your bequest, annuity, or other planned gift further strengthens the foundation of all our conservation work, giving future generations the tools they'll need for a changing world.

Please let us know when you include The Peregrine Fund in your plans. Use the form at www.peregrinefund.org/legacy-circle, e-mail us at legacycircle@peregrinefund.org or call 406-388-7717.

Members and donors are the lifeblood of The Peregrine Fund, and we respect and appreciate everyone who contributes to our mission. To protect your privacy, we do not publish a general membership list.

We welcome your calls and emails if you have questions about your membership. Linda Behrman, our Director of Membership, is available at **208-362-3716** or lbehрман@peregrinefund.org.

Leadership Council members remain crucial to our success by giving \$1,000 or more annually. In addition to regular member benefits, they receive a personalized desktop paperweight, invitations to board meetings and special events, one Gift Membership to give, a behind-the-scenes tour at the World Center for Birds of Prey, quarterly updates from the President, and recognition in the annual report. Learn more at www.peregrinefund.org/leadership-council.
